

## K9IVB Version Of Sam Wetterlin Calibration Source

This is a brief response to a Yahoo Group Softrock 40 Post referring to one of Sam's original designs.

I have Modified the PCB to fit my needs and posted a link on OSH Park website for sharing the Gerbers or ordering boards.

I have been quite busy and will not get time to assemble my boards until mid September.

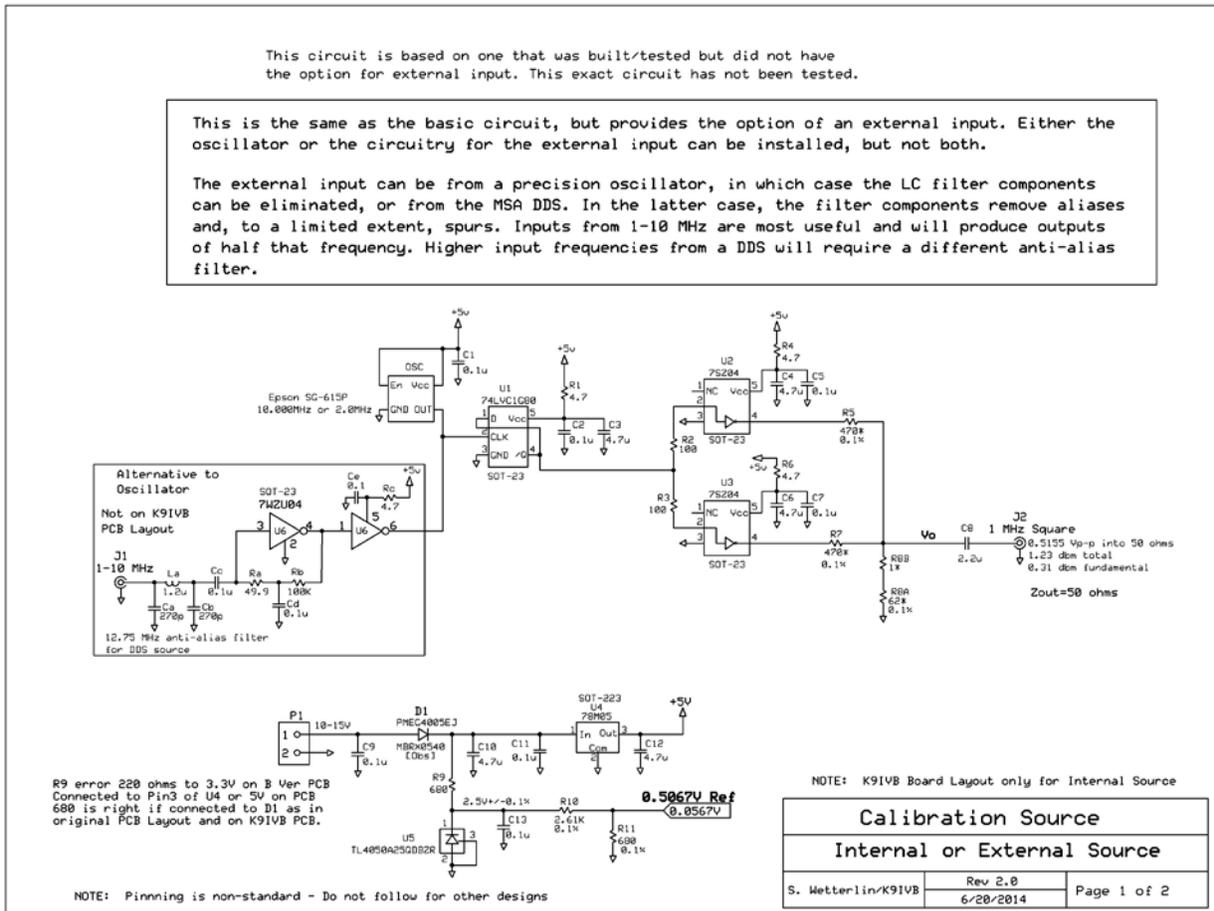

After finishing my build I will update this document.

What Follows is the revised Schematic and BOM.

The OSH Park link is:

Dick K9IVB

**Theory behind using DC output voltage to determine AC peak-to-peak output**

The ideal square wave from the inverters, combined with their actual output impedance and the voltage divider at the output can be combined into a Thevenin equivalent voltage source driving a 50-ohm resistor to the output. (50-ohms is accurate so long as the inverter output impedance is in the range 0-30 ohms.)

DC Analysis: Average value of  $V_o$  will adjust so that current inflow through  $R_s$  during square wave peak will equal current outflow through  $R_s$  during square wave 0V value. Due to 50% duty cycle, the DC value of  $V_c$  will equal  $V_s/2$ . This value is independent of  $R_L$ .

AC analysis:  $V_o$  will always equal  $V_s/2$  because  $R_s=R_L$ .

Therefore square wave peak-to-peak = DC value at  $V_c$

**Calibration Procedure (Use any voltmeter with 5% or better accuracy and 1 mV resolution.)**

Determine the DC voltage at  $V_o$  by measuring the difference between the voltage reference and  $V_o$ . Call that voltage  $V_{dc}$ .  $V_{dc}$  will also turn out to be the peak-to-peak square wave voltage for a 50-ohm load. The stated output levels assume  $V_{dc}=0.5155V$ . Determine the deviation of your  $V_{dc}$  from 0.5155V in millivolts. For each millivolt of deviation adjust all the output values stated in dbm by 0.017 dbm. (This is accurate for deviations of a few percent.)

The adjustment is positive if  $V_{dc}>0.5155$ ; otherwise it is negative. Round results to nearest 0.1 dbm.

As a precaution against the possibility that a voltmeter may give an inaccurate DC reading due to the presence of an AC signal, the output can be shorted at the right side of C8.
